

EVIDENCE SUMMARY

Should remdesivir be used in the treatment of children with COVID-19 infection?

Evidence Reviewers: Melissa A. Dator, MD, Ma. Lucila M. Perez, MD, MSc, FPPS, Maria Teresa S. Tolosa, MD, FPDS, DipCE; Leonila F. Dans, MD, MS

Recommendation

1. We suggest the use of remdesivir in hospitalized children with severe COVID-19 infection.

Certainty of Evidence: Very low

Strength of Recommendation: Weak

2. We suggest the use of remdesivir in non-hospitalized children with COVID-19 infection with at least 1 risk factor for disease progression.

Certainty of Evidence: Low

Strength of Recommendation: Weak

Consensus Issues

The recommendations were based on the evidence from one observational study among pediatric patients and 10 randomized controlled trials among patients aged 12 years old and above.

Despite the very low certainty of evidence for hospitalized children, the panel voted for the use of remdesivir. This is due to the significant benefit in decreasing the risk for clinical deterioration (based on WHO progression scale) and the risk reduction in mechanical ventilation use, although this was not statistically significant. The panel also agreed that because there are very limited treatment options for pediatric patients with COVID-19, this would give better guidance to clinicians. The panel emphasized though that remdesivir should be used for pediatric patients with severe COVID-19 following the classification of PIDSP and PSMID (on low flow oxygen support).

The panel voted for the use of remdesivir in non-hospitalized children with COVID-19 infection based on the evidence from one double-blind, placebo controlled randomized controlled trial done among patients aged 12 years old and above. This study showed significant benefit in preventing COVID-19 related hospitalization or all-cause mortality. Remdesivir was given to the patients 7 days from symptom onset and to those with at least one of the following risk factors: hypertension, cardiovascular or cerebrovascular disease, diabetes mellitus, obesity, immune compromise, chronic mild or moderate kidney disease, chronic liver disease, chronic lung disease, current cancer or sick cell disease.

Key Findings

- There are no randomized controlled trials (RCTs) to evaluate the use of remdesivir in the treatment of COVID-19 in the pediatric population.
- One observational study (n=77) among pediatric patients described the compassionate use of Remdesivir for all 77 patients. It showed 83% of cases recovered after 28 days of

Philippine Pediatric COVID-19 Living Clinical Practice Guidelines

follow-up. On subgroup analysis, those on invasive ventilation took a significantly longer time to recover and time to discharge than those without, with 32% of patients presenting at least 1 adverse event.

- Pooled results of ten RCTs evaluating the use of Remdesivir in adults outpatients with mild to moderate COVID-19 with risk factors has shown significant benefit in terms of reducing risk for hospitalizations and death. For hospitalized/in-patients, Remdesivir decreased the risk only for clinical deterioration as measured by the WHO progression scale but did not show benefit in other outcomes: all-cause mortality, need for mechanical ventilation and time to clinical improvement. No increased risk of adverse events and serious adverse events were noted. Overall certainty of evidence was rated low to very low due to serious risk of bias, inconsistency, indirectness and imprecision.

Introduction

Remdesivir is an antiviral drug administered intravenously that has been shown to inhibit viral replication. This was initially developed for the Ebola virus and is currently being evaluated as a potential treatment for COVID-19 infection [1].

Previously published RCTs on the use of remdesivir for adult patients with moderate to severe COVID-19 had shorter time to recovery and a lower risk of progression to more severe respiratory disease, safety profiles were similar to placebo and may have greater efficacy when initiated early. Pediatric approval by the US FDA for its use on those 12 years old and above or and weighing ≥ 40 kg was extrapolated from adult trials with pharmacokinetic modeling and safety profile expected to be comparable to adults [2].

Review Methods

A systematic search was done until January 20, 2022 using free text and MeSH terms for coronavirus, SARS-COV-2, COVID-19 in children and remdesivir. The inclusion criteria for this review may be found in Table 1. Only RCTs and observational analytic studies were included. Pubmed, Cochrane Library, Google scholar and COVID-NMA were sought. Preprints were also checked in the medRxiv database. Ongoing studies were also searched in NIH clinicaltrials.gov. Relevant cited references were also manually searched.

Table 1. PICO criteria for remdesivir and COVID-19.

Population	Children with COVID-19
Intervention/Exposure	Remdesivir
Comparison	Usual care, standard of care, placebo, any active control
Outcomes	Hospitalization, mortality, recovery, clinical improvement, need for mechanical ventilation, duration of hospital or ICU stay, adverse events, time to negative viral conversion

Since few to no studies were seen in children on Remdesivir, the Philippine COVID-19 Living Clinical Practice Guidelines (LCPG) Phase 1 on adults was also reviewed as indirect evidence. To update the LCPG, newer clinical trials on the use of remdesivir in adult patients were also included. Available meta-analysis from the COVID-NMA was incorporated in this review. The observational analytic study was appraised using the Newcastle-Ottawa Scale (NOS), Cochrane RoB II for RCTs and AGREE II tool for CPGs. Sub-group analysis by age, dose and severity were done.

Results

The only study on children was a multi-center cohort done in various countries (United States, Spain, United Kingdom, Italy, France and Germany) which included 77 pediatric patients with severe COVID-19 infection who all received Remdesivir through a compassionate use program. There was no control group. The median age was 14 years old (range <2 months to 17 years [IQR 7-16]), 51% (39/77) were on invasive ventilation and 79% (61/77) had at least 1 co-morbid medical condition. A 10-day course was recommended with the following dosing regimen:

- >40kg: Loading dose of 200mg intravenously then 100mg intravenously subsequent days.
- < 40kg: Loading dose of 5mg/kg intravenously on day 1 then 2.5mg/kg/intravenously on subsequent days

Only 62% (48/77) received all 10 doses of Remdesivir in this study. Concomitant medications (hydroxychloroquine, methylprednisolone, anakinra, tocilizumab, hydrocortisone and dexamethasone) were also given to some of the study participants. The study was assessed to be of fair quality using the Newcastle Ottawa Scale.

In 83% (64/77) of patients, there was recovery after 28 days of follow-up. Subgroup analysis by requirement for invasive mechanical ventilation at baseline and age (≤ 12 and > 12 years) were done. Those on invasive ventilation at baseline had significantly longer time to recovery (HR 0.47, 95% CI 0.28-0.78) than those without. The patients aged ≤ 12 years old also showed significantly longer time to recovery (HR 0.54, 95% CI 0.33-0.89 compared to older cases).

Of 77 patients, 32% experienced at least 1 adverse event. Risk for adverse events was comparable regardless if they were on non-invasive ventilation or not. Adverse events reported were elevated ALT and AST level and anemia. Serious adverse events were elevations in transaminase levels (grade 3 and 4 elevations) and renal adverse events (hematuria, elevations in creatinine levels, toxic nephropathy and renal impairment). Four deaths (4/77, 5%) were reported in this study, all of whom received 9-10 days of remdesivir.

The Philippine COVID-19 LCPG) Phase 1 on adults had a favorable assessment using AGREE Scale. The trials were further updated with 6 new trials resulting in a total of ten (10) RCTs done in adults included in this review (N=10,454) [4-13]. Remdesivir was compared to placebo in three trials [8-9,12] and local standard of care in seven [4-7,10-11,13]. Some treatment interventions used for standard of care included corticosteroids [5-7,10-11,13], anti-coagulation [5,10], antivirals [11] and immunomodulators [5,11]. Nine trials recruited patients with COVID-19 that required hospitalization while one trial focused on non-hospitalized COVID-19 patients [9]. The studies with hospitalized patients included those with mild to critical COVID. Eight RCTs used a 10-day course of Remdesivir while two studies used a 5-day course [10-11]. The study on out-patient use used a 3-day course. The primary outcome of the studies was all-cause mortality, with duration of follow up ranging from 24 to 90 days. Other outcomes reported were time to clinical improvement, need for mechanical ventilation, need for ICU admission, adverse events and serious adverse events. Appendix 2 shows the characteristics of all the included studies.

The overall certainty of evidence was rated to be very low due to serious risk of bias, inconsistency, indirectness and imprecision. The serious risk of bias was mostly due to performance bias, as most of the trials were open label/unblinded as well as detection bias and attrition bias. See risk of bias summary and GRADE evidence summary in Appendix 3-5.

Hospitalized patients

Mortality

Pooled results among nine RCTs (N=9,891) showed that Remdesivir had no effect on all-cause mortality at day 28 (RR 0.91, 95 % CI 0.82-1.01) among adult patients.

Subgroup analysis among adult patients with mild-moderate disease (no oxygen support requirement) at baseline had inconclusive results (RR 0.86, 95% CI 0.55-1.36). Patients with severe disease (those on low flow oxygen support) also did not show significant benefit (RR 0.69, 95% CI 0.41-1.13. $I^2=55%$). There was no effect among patients with critical disease (those on high flow oxygen support, NIV, mechanical ventilation or ECMO) (RR 1.00, 95% CI 0.87-1.14).

Sub group analysis by treatment duration showed inconclusive effect on mortality for those on the 5-day treatment regimen (RR 0.98, 95% CI 0.37, 2.56; $I^2=0%$) and no effect for those given the 10-day treatment regimen (RR 0.92, 95% CI 0.83, 1.03; $I^2=0%$).

Clinical Improvement

Pooled results in four RCTs on adult cases showed that the rate of clinical improvement up to day 28 among those given Remdesivir was comparable to those given placebo or standard treatment (RR 1.07, 95% CI 1.01, 1.13). There was no significant effect seen on time to clinical improvement (RR 1.07, 95% CI 0.91, 1.27; $I^2=50.7%$) as well. However, a decreased risk for clinical deterioration as measured by the WHO progression scale (RR 0.75, 95% CI 0.62,0.89) was reported.

Remdesivir has also shown a reduction in the risk for mechanical ventilation which was not statistically significant and had considerable heterogeneity (RR 0.75, 95% CI 0.56, 1.02; $I^2=82%$). There is an inconclusive risk for ICU admission (RR 0.98, 95% CI 0.43, 2.22; 1 RCT, n=181).

Non-hospitalized patients

One double-blind placebo-controlled RCT involved 562 non-hospitalized adult patients 12 years old and above with COVID-19, with symptom onset in the previous 7 days and had at least one risk factor for disease progression]. Risk factors included hypertension, cardiovascular or cerebrovascular disease, diabetes mellitus, obesity, immune compromise, chronic mild or moderate kidney disease, chronic liver disease, chronic lung disease, current cancer or sickle cell disease. [7] A 3-day course of Remdesivir was given in the intervention group (200mg on Day 1 and 100 mg on day 2 and 3). Overall certainty of evidence for this study was low due to serious indirectness and imprecision. Remdesivir showed a significant benefit in preventing COVID-19 related hospitalization or death from any cause (RR 0.13, 95% CI 0.03, 0.6).

There were eight pediatric patients included in the RCT (3 on remdesivir and 5 on placebo group). Subgroup analysis on these children showed inconclusive results for COVID-19 related hospitalization or death from any cause (RR 1.5, 95% 0.03, 61.3) and safety with mild-moderate COVID-19 (RR 0.58, 95% 0.03-11.2). Only one pediatric patient (placebo group) reported mild fatigue. There were no COVID-19 related hospitalization or death from any cause by Day 28.

Negative Viral Conversion

Remdesivir showed no benefit for negative viral conversion by Day 7 of illness (RR 1.02, 95% 0.76-1.38; 1 RCT n = 196).

Safety

Remdesivir showed no significant risk for adverse events (RR 0.99, 95% CI 0.92, 1.08; $I^2=31%$) and serious adverse events (RR 0.84, 95% CI 0.67, 1.04; $I^2=49%$) in hospitalized patients. In the out-patient study, there was also no significant risk for adverse events (RR 0.91, 95% CI 0.75,1.1) but it showed a significant decreased risk for serious adverse events (RR 0.26 95%CI 0.10,0.70). The most common adverse events reported were nausea, headache, cough, diarrhea, dyspnea, fatigue, pyrexia, increased creatinine level, decreased glomerular filtration rate, hypersensitivity reactions and elevation in hepatic enzymes. Serious adverse events included respiratory failure, cardiopulmonary failure and renal failure necessitating kidney replacement therapy

Other Considerations (Evidence to Decision)

Remdesivir is available locally as 100mg of lyophilized powder for reconstitution in a single-use vial, under a compassionate special permit (CSP) for use in the treatment of COVID-19 [14]. The suggested retail price specified in a DOH memorandum is up to Php 8,200 per 100mg vial [15]. Following the recommended dosing of 200mg IV on Day 1 and 100mg IV on Days 2 to 10 for a 10-day course, the total cost per patient (at the SRP) is Php 90,200.00. For outpatient therapy, the total cost per patient is Php 32,800 for the recommended 3-day course. Cost effectiveness and cost utility analysis in the United States showed that remdesivir is more costly and less effective for the treatment of severe COVID-19 compared to Dexamethasone, while in South Africa and Turkey it saved costs by reducing the number of ICU days with higher QALYs [16-18].

Remdesivir has been granted emergency use authorization by the US FDA for the treatment of COVID-19 in adults and children more than 12 years old and weighing at least 40kg. The US NIH recommendations noted that administering IV infusions of remdesivir for up to 5 consecutive days can be difficult in the outpatient setting.

Recommendations from Other Groups

Table 2. Summary of recommendations from other groups

Society/ Regulatory Agency	Recommendation
US NIH • February 1, 2022 • February 24, 2022	Recommended for: <ul style="list-style-type: none">• Non-hospitalized children aged ≥ 12 years and weighing ≥ 40 kg at high risk of disease progression, initiate treatment as soon as possible and within 7 days of symptom onset;• Hospitalized children aged ≥ 12 years with COVID-19 who have risk factors for severe disease and have an emergent or increasing need for supplemental oxygen• Hospitalized children aged ≥ 16 years with COVID-19 who have an emergent or increasing need for supplemental oxygen regardless of whether they have risk factors for severe disease

Philippine Pediatric COVID-19 Living Clinical Practice Guidelines

	<p>In consultation with a pediatric infectious disease specialist, remdesivir can be considered for hospitalized children of all ages with COVID-19 who have an emergent or increasing need for supplemental oxygen</p>
<p>Pediatric Infection Disease Society - USA (September 12, 2020)</p>	<p>Outpatients and hospitalized patients with asymptomatic, mild, or moderate COVID-19 should be managed with supportive care only. Remdesivir should be used only within the context of a clinical trial in these populations.</p> <p>Remdesivir is <u>suggested for</u> children with severe COVID-19.</p> <p>Remdesivir should be considered for children with critical COVID-19, unless there are contraindications.</p> <ul style="list-style-type: none">• Severe COVID-19: recommended duration of up to 5 days of remdesivir therapy for children.• If used for children with critical COVID-19, a duration of 5-10 days is suggested; consider on a case-by-case basis for children not improving after 5 days of therapy.
<p>National COVID-19 Clinical Evidence Taskforce – Australia October 24, 2021</p>	<p>Use of remdesivir for children or adolescents with COVID-19 outside a trial setting should not be routinely considered (Low certainty of evidence, Conditional)</p>
<p>Philippine COVID Living CPG (March 2021)</p>	<p>We suggest:</p> <ul style="list-style-type: none">• against the use of remdesivir in patients with COVID-19 infection who have O₂ saturation >94% and do not require oxygen supplementation* ; also in patients with COVID-19 infection who are already on invasive mechanical ventilation*. <p>for addition of remdesivir to dexamethasone in patients with COVID-19 infection who have O₂ saturation ≤ 94% and/or requiring oxygen supplementation*.</p> <p>* All low certainty of evidence, conditional recommendation</p>
<p>WHO November 20, 2020</p>	<p>Recommend against remdesivir in COVID-19 hospitalized patients. There is no evidence showing improvement in survival or other outcomes.</p>

Research Gaps

Current clinical recommendations on the use of remdesivir have been based on efficacy and safety profiles in trials done among adult patients. There is one ongoing randomized controlled trial that is currently ongoing on the pharmacokinetics and safety of its use in the pediatric population. An update of this review will be done once the results are available.

Appendix 3. Study Appraisal

Goldman et al (May 2021) – **Fair Quality**

Table 1. Newcastle-Ottawa Quality Assessment Form for Cohort Studies Selection

- 1) Representativeness of the exposed cohort
 - a) Truly representative (*one star*) *
 - b) Somewhat representative (*one star*)
 - c) Selected group
 - d) No description of the derivation of the cohort
- 2) Selection of the non-exposed cohort
 - a) Drawn from the same community as the exposed cohort *
 - b) Drawn from a different source
 - c) No description of the derivation of the non exposed cohort
- 3) Ascertainment of exposure
 - a) Secure record (e.g., surgical record)
 - b) Structured interview (*one star*)
 - c) Written self report
 - d) No description
 - e) Other
- 4) Demonstration that outcome of interest was not present at start of study
 - a) Yes (*one star*)
 - b) No

Comparability

- 1) Comparability of cohorts on the basis of the design or analysis controlled for confounders
 - a) The study controls for age, sex and marital status (*one star*) *
 - b) Study controls for other factors (list) _____ (*one star*)
 - c) Cohorts are not comparable on the basis of the design or analysis controlled for confounders

Outcome

- 1) Assessment of outcome
 - a) Independent blind assessment (*one star*)
 - b) Record linkage (*one star*)
 - c) Self report
 - d) No description
 - e) Other
- 2) Was follow-up long enough for outcomes to occur
 - a) Yes (*one star*) *
 - b) No

Indicate the median duration of follow-up and a brief rationale for the assessment above: 28 day follow up

- 3) Adequacy of follow-up of cohorts
 - a) Complete follow up- all subject accounted for (*one star*) *
 - b) Subjects lost to follow up unlikely to introduce bias- number lost less than or equal to 20% or description of those lost suggested no different from those followed. (*one star*)
 - c) Follow up rate less than 80% and no description of those lost
 - d) No statement

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias)	Blinding of outcome assessment (detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias

Question: Should remdesivir compared to placebo or standard of care be used in the treatment for COVID-19 hospitalized patients?

Certainty assessment							No of patients		Effect		Certainty	Importance
No of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Remdesivir	Placebo or Standard of Care	Relative (95% CI)	Absolute (95% CI)		

Mortality (Day 28)

9	randomised trials	serious ^a	not serious	serious ^b	not serious	none	554/5092 (10.9%)	591/4799 (12.3%)	RR 0.91 (0.82 to 1.01)	11 fewer per 1,000 (from 22 fewer to 1 more)	⊕⊕○○ Low	Critical
---	-------------------	----------------------	-------------	----------------------	-------------	------	------------------	------------------	----------------------------------	--	-------------	----------

Mortality (Day 28) - 5 day Remdesivir

2	randomised trials	serious ^a	not serious	serious ^b	serious ^c	none	8/232 (3.4%)	7/141 (5.0%)	RR 0.98 (0.37 to 2.56)	1 fewer per 1,000 (from 31 fewer to 77 more)	⊕○○○ Very low	Critical
---	-------------------	----------------------	-------------	----------------------	----------------------	------	--------------	--------------	----------------------------------	--	------------------	----------

Mortality (Day 28) - 10 day Remdesivir

8	randomised trials	serious ^a	not serious	serious ^b	not serious	none	546/4848 (11.3%)	575/4658 (12.3%)	RR 0.92 (0.83 to 1.03)	10 fewer per 1,000 (from 21 fewer to 4 more)	⊕⊕○○ Low	Critical
---	-------------------	----------------------	-------------	----------------------	-------------	------	------------------	------------------	----------------------------------	--	-------------	----------

Clinical Improvement

4	randomised trials	serious ^a	not serious	serious ^b	not serious	none	715/1024 (69.8%)	455/748 (60.8%)	RR 1.07 (1.01 to 1.13)	43 more per 1,000 (from 6 more to 79 more)	⊕⊕○○ Low	Critical
---	-------------------	----------------------	-------------	----------------------	-------------	------	------------------	-----------------	----------------------------------	--	-------------	----------

Clinical Deterioration (WHO Progression Score)

Philippine Pediatric COVID-19 Living Clinical Practice Guidelines

Certainty assessment							No. of patients		Effect		Certainty	Importance
No. of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Remdesivir	Placebo or Standard of Care	Relative (95% CI)	Absolute (95% CI)		
5	randomised trials	serious ^d	not serious	serious ^b	not serious	none	189/1565 (12.1%)	229/1269 (18.0%)	RR 0.75 (0.62 to 0.89)	45 fewer per 1,000 (from 69 fewer to 20 fewer)	⊕⊕○○ Low	Important

Need for Mechanical Ventilation

5	randomised trials	serious ^a	serious ^a	serious ^b	serious ^c	none	516/4271 (12.1%)	614/4196 (14.6%)	RR 0.75 (0.56 to 1.02)	37 fewer per 1,000 (from 64 fewer to 3 more)	⊕○○○ Very low	Critical
---	-------------------	----------------------	----------------------	----------------------	----------------------	------	------------------	------------------	---------------------------	---	------------------	----------

Negative Viral Conversion

1	randomised trials	serious ^f	not serious	serious ^b	serious ^c	none	66/131 (50.4%)	32/65 (49.2%)	RR 1.02 (0.76 to 1.38)	10 more per 1,000 (from 118 fewer to 187 more)	⊕○○○ Very low	Important
---	-------------------	----------------------	-------------	----------------------	----------------------	------	----------------	---------------	---------------------------	---	------------------	-----------

Serious Adverse Events

5	randomised trials	serious ^g	not serious	serious ^b	serious ^c	none	329/2158 (15.2%)	346/1875 (18.5%)	RR 0.84 (0.67 to 1.04)	30 fewer per 1,000 (from 61 fewer to 7 more)	⊕○○○ Very low	Critical
---	-------------------	----------------------	-------------	----------------------	----------------------	------	------------------	------------------	---------------------------	---	------------------	----------

Adverse Events

5	randomised trials	serious ^g	not serious	serious ^b	not serious	none	941/2158 (43.6%)	790/1875 (42.1%)	RR 0.99 (0.92 to 1.08)	4 fewer per 1,000 (from 34 fewer to 34 more)	⊕⊕○○ Low	Critical
---	-------------------	----------------------	-------------	----------------------	-------------	------	------------------	------------------	---------------------------	---	-------------	----------

CI: confidence interval; RR: risk ratio

Explanations

- Some trials with issues on randomization, missing outcome data, performance bias and detection bias
- Trials done on adult patients only. No pediatric patients enrolled
- Wide confidence interval
- 1 study assessed to have overall high risk of bias
- Considerable heterogeneity ($I^2 = 82\%$)
- Missing outcome data
- Studies had deviations from intended intervention, missing outcome data and reporting bias

Philippine Pediatric COVID-19 Living Clinical Practice Guidelines

Appendix 5B. GRADE Evidence Profile: Non-hospitalized Patients

Author(s): Melissa A. Dator, MD, Maria Teresa S. Tolosa, MD, FPDS, DipCE; Ma. Lucila M. Perez, MD, MSc, FPPS

Question: Should remdesivir compared to placebo or standard of care be used in the treatment for COVID-19 non-hospitalized patients?

Bibliography: Gottlieb R, 2022

Certainty assessment							№ of patients		Effect		Certainty	Importance
№ of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Remdesivir	Placebo	Relative (95% CI)	Absolute (95% CI)		
COVID-19 related hospitalization or death from any cause - Day 28												
1 (N=568)	randomised trials	not serious	not serious	serious ^a	serious ^b	none	2/279 (0.7%)	15/283 (5.3%)	RR 0.13 (0.03 to 0.60)	46 fewer per 1,000 (from 51 fewer to 21 fewer)	⊕⊕○○ Low	Critical
Adverse events												
1 (N=568)	randomised trials	not serious	not serious	serious ^a	serious ^b	none	118/279 (42.3%)	131/283 (46.3%)	RR 0.91 (0.75 to 1.10)	42 fewer per 1,000 (from 116 fewer to 46 more)	⊕⊕○○ Low	Critical
Serious adverse events												
1 (N=568)	randomised trials	not serious	not serious	serious ^a	serious ^b	none	5/279 (1.8%)	19/283 (6.7%)	RR 0.26 (0.10 to 0.70)	50 fewer per 1,000 (from 60 fewer to 20 fewer)	⊕⊕○○ Low	Critical
COVID-19 related hospitalization or death from any cause - Pediatric only												
1 (N=8)	randomised trials	not serious	not serious	not serious	very serious ^b	none	0/3 (0.0%)	0/5 (0.0%)	RR 1.50 (0.03 to 61.30)	0 fewer per 1,000 (from 0 fewer to 0 fewer)	⊕⊕○○ Low	Critical

Philippine Pediatric COVID-19 Living Clinical Practice Guidelines

Adverse Event - Pediatric only												
1 (N=8)	randomised trials	not serious	not serious	not serious	serious ^a	none	0/3 (0.0%)	1/5 (20.0%)	RR 0.58 (0.03 to 11.20)	84 fewer per 1,000 (from 194 fewer to 1,000 more)	 Moderate	Critical

CI: confidence interval; RR: risk ratio

Explanations

- Majority of the population in the study were adults. Only 8 patients were below 18 years old.
- Wide confidence interval
- Target sample size of 1264 not met
